

ERP Integration Guide: Full CU Clubs Portal

This document provides instructions for integrating the "Full Portal" package (`erp_ready_portal.zip`) into your ERP or university ecosystem. This package contains the entire suite of front-end pages, including the admin dashboard.

1. Directory Structure Overview

- `clubs.html` & `clubv2.html` : Main user-facing portals for exploring clubs.
- `index.html` , `communities.html` , `departmental-societies.html` , `professional-societies.html` : Related university life pages.
- `clubs.json` : The single source of truth database. All portal pages read from this file.
- `admin/` : The front-end admin dashboard used for updating `clubs.json` .
- `api/` : Vercel serverless functions (Node.js) currently used by the admin dashboard to authenticate and push updates directly to GitHub.
- `latest-assets/` , `new-assets/` , `campus-life/` , `includes/` : Essential CSS/JS dependencies.
- `logos/` & `media/` : Stored images for the clubs.

2. Integration Strategy

The portal is designed to be fully static and locational-independent. You can extract the contents into any sub-directory on your web server (e.g., `https://your-domain.edu/erp/student-life/`). All internal file references are relative (`./`) and will resolve correctly without any configuration.

Serving the Content

No specialized Node.js or Python server is required to serve the frontend pages. You can use standard Apache, Nginx, or IIS configurations to serve the HTML.

Managing Data (`clubs.json`)

The entire application state is driven by `clubs.json` . To modify the clubs displayed on the portal, you only need to overwrite `clubs.json` .

3. Adapting the Admin Dashboard

By default, the included `admin/app.js` sends REST requests to `/api/clubs` and `/api/upload` to securely modify the GitHub repository via Vercel serverless functions.

Because you are integrating this into an ERP system, you will likely want to replace this GitHub-based storage with your own database (e.g., MySQL/PostgreSQL).

Steps to adapt the admin panel to your backend:

1. Ignore or delete the `api/` folder.
2. Open `admin/app.js` .
3. Locate the `saveClubsData()` and `uploadFile()` functions.
4. Modify the `fetch()` calls to hit your ERP's custom API endpoints (e.g., PHP or Java controllers).
5. Ensure your ERP's API endpoint writes the updated JSON payload to `clubs.json` on the server so that `clubs.html` automatically reflects the changes.

4. Security Notes

- The provided code contains no hardcoded API keys, secrets, or GitHub tokens.
- Ensure that the `/admin` folder is placed behind your ERP's authentication middleware to prevent unauthorized students from modifying club data.
